3512 – Tutorial 1 – Jan 16

Exercise 1:

Objective

Practice creating an HTML form using correct structure, attributes, and input types.

Instructions

Create an empty index.php file in your working directory.

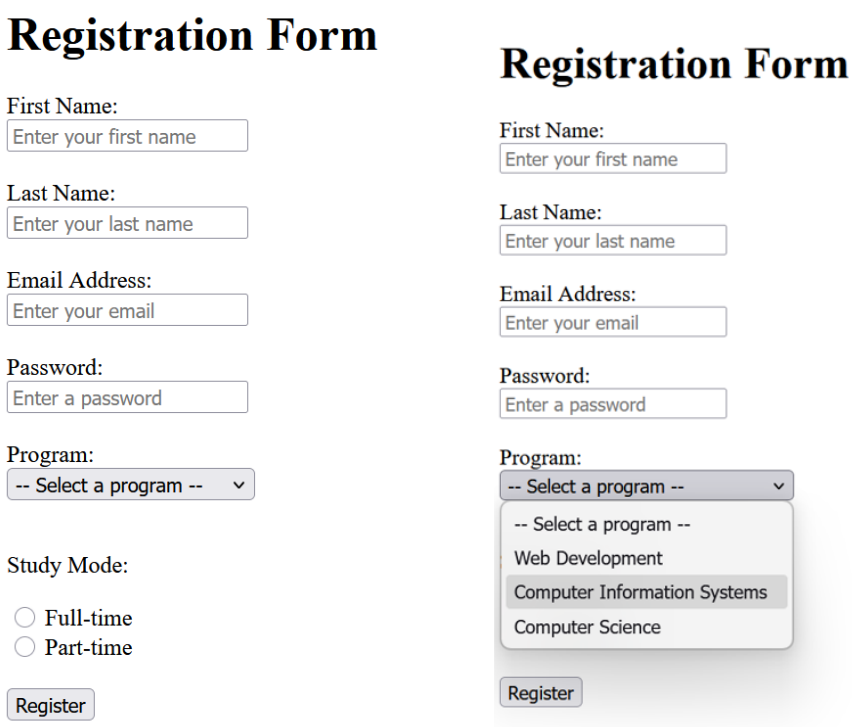

Download given "process.php" file from D2L (Individual Tutorial 1 folder) and save it in the same folder as index.php.

Write an HTML code in your index.php file to contain a form with the following requirements:

1. The form must use the **POST** method.
2. Set the **action** attribute to: process.php
3. The form must include the following fields:
    - A text input for **First Name**
    - A text input for **Last Name**
    - An email input for **Email Address**
    - A password input for **Password**
    - A select input for **program selection**
    - Two radio buttons input for **study mode**

4. Each input field must:
    - Have an associated <label>
    - Include a meaningful name attribute
5. Add a **Submit** button labeled **"Register"**

The result form should look like this:

After clicking Register button a page should be displayed like the following with your entered information in the form instead. The following shows my entered information in the form. Yours can be different.

Form Data Received

```
Array
(
    [firstName] => Fatemeh
    [lastName] => Shirzad
    [email] => fshirzad@mtroyal.ca
    [password] => mypassword1234
    [program] => web
    [studyMode] => full-time
)
```

Checklist: Ensure that your final code has all the following criteria:

- Correct <form> tag with action and method
- All required input fields present
- Proper use of label and name attributes
- Valid HTML structure
- Form submits successfully

Exercise 2

For this exercise, first write your solution on paper without using any IDE, as IDEs may provide AI-generated hints. Keep in mind that quizzes and exams will be written on paper, so practicing this way is important. After completing your solution on paper, you may then write the code in an IDE to test and verify your work.

```
$filename = "happy.jpg";
$alt = "happy life";
$classname = "box";
// markup: <img src='images/happy.jpg' alt='happy life' class='box' />
```

Given the above code, create an empty "index.php" file and copy and paste the code in the file. Then echo a proper <img> element using both the concatenation (using the . operator) and the embedded variable (variables within double quotes) approach so that the commented markup is generated.

The image file "happy.jpg" has been provided on D2L under the "Individual Tutorial 1" folder. Download and save "happy.jpg" in an "images" subfolder under your project directory in your Github repository.

Test your code by running PHP and opening the browser.

Exercise 3

For this exercise, first write your solution on paper without using any IDE, as IDEs may provide AI-generated hints. Keep in mind that quizzes and exams will be written on paper, so practicing this way is important. After completing your solution on paper, you may then write the code in an IDE to test and verify your work.

```
$url = "https://www.google.com";
$linkText = "Visit Google";
$target = "_blank";

// markup: <a href="https://www.google.com" target="_blank">Visit Google</a>
```

Given the above code, create an empty index.php file and copy and paste the code into the file. Then echo a proper <a> element using both of the following approaches so that the commented markup is generated:

1. String concatenation using the . operator
2. Embedded variables (variables inside double quotes)

Save the file and test your code by running PHP and opening the file in your browser.
